A handheld classroom dashboard: Teachers' perspectives on the use of real-time collaborative learning analytics

Roberto Martinez-Maldonado¹

Received: 2 August 2018 / Accepted: 11 October 2019 © International Society of the Learning Sciences, Inc. 2019

Abstract

In Computer-Supported Collaborative Learning (CSCL) classrooms it may be challeng-13ing for teachers to keep awareness of certain aspects of the learning process of each small 14 group or assess whether the enactment of the class script deviates from the original plan. 15Orchestration tools, aimed at supporting the management of the increasing uncertainty 16and complexity of CSCL classrooms, have been emerging in response. Similarly, learning 17 analytics innovations hold the promise of empowering teachers by making certain aspects 18of the classroom visible and by providing information that can prompt actionable 19responses. However, the active role that data may play in teachers' decision-making 20and orchestration processes is still not well understood. This paper investigates the 21perspectives of teachers who used a real-time analytics tool to support the orchestration 22of a CSCL classroom. A longitudinal study was conducted with a handheld dashboard 23deployed in a multi-display collaborative classroom during one full academic term. The 24dashboard showed real-time information about group participation and task progress; the 25current state of the CSCL script; and a set of text notifications informing teachers of 26potential students' misconceptions automatically detected. The study involved four 27teachers conducting 72 classroom sessions during 10 weeks with a total of 150 students. 28The teachers' perspectives discussed in this paper portray the promises and challenges of 29introducing new technologies aimed at enhancing orchestration and awareness in a CSCL 30 classroom. 31

Introduction

35

It is not uncommon for educators to promote the development of collaboration skills by 36 designing and conducting a variety of small group learning tasks in the classroom (Bishop and 37 Verleger 2013; Prieto et al. 2015b). The spatial affordances of the classroom allows students to 38 interact with their peers; perceive and be perceived by others; and generate knowledge and 39understanding while being closely coached by teachers (Chen et al. 2010; Ni 2013; Stodel 40et al. 2006). The effective deployment and assessment of collocated collaborative learning 41 tasks is only going to become more critical because collaboration and help-seeking from peers 42are playing an important role in education (O'Donnell and Hmelo-Silver 2013) and for the 43development of twenty-first century skills (Beetham and Sharpe 2013; Buckingham Shum and 44 Crick 2016). 45

In the last couple of decades, emerging classroom technologies have gained considerable 46attention to promote the development of collocated collaboration skills (Chen et al. 2010; 47 Sottilare et al. 2018; Stahl et al. 2006; Stahl 2017). However, it may be hard for teachers to 48 keep awareness of what is going on within each small group in the classroom (Alavi et al. 492009; Gutiérrez Rojas et al. 2012; Liu and Nesbit 2019) or have a detailed sense of how the 50task is unfolding according to the original plan (Hernández-Leo et al. 2019; Mangaroska and 51Giannakos 2018). A number of technologies have been developed to facilitate collaborative 52learning in the classroom. For example, Computer-Supported Collaborative Learning (CSCL) 53technologies that provide scripting or scaffolding support have been created with the aim of 54maximising students' opportunities for learning and developing effective collaboration strat-55egies (Fischer et al. 2007; Ludvigsen et al. 2016). However, the reality is that it may become 56increasingly challenging for teachers to *orchestrate* these technologies on top of the epistemic, 57social, and pedagogical aspects of the classroom that they also need to manage (Chen et al. 582009; Dillenbourg 2013; Dimitriadis 2012; Munoz-Cristobal et al. 2015). In response, orches-59tration technologies have emerged in recent years to help teachers manage the increasing 60 uncertainty and complexity of CSCL classrooms (Dimitriadis 2012). 61

Classroom orchestration can be described as a regulation loop that consists of two main 62 tasks: state awareness and workflow manipulation (Dillenbourg et al. 2011). In recent years, 63 some of the practical orchestration tasks that teachers must accomplish have also been targeted 64 by the fast-growing area of learning analytics (LA) (Greller and Drachsler 2012; Scheffel et al. 652014) by exploiting the digital traces that learners may leave behind while collaborating. 66 Dashboards and similar data-intensive applications (such as automated alarms, recommenders 67 68 or personalised feedback tools) have gained considerable attention as mechanisms that can be used to enhance awareness and make the orchestration of CSCL classrooms more effective 69 (Prieto et al. 2018). 70

Particularly, teacher-facing dashboards are intended to help educators gain a better under-71standing of their whole course; reflect on their teaching strategies; or identify learners who 72may require specific attention (Molenaar and Campen 2017; Verbert et al. 2013). However, 73although the dashboard metaphor is appealing, some barriers to adoption have already been 74identified, including the potential misalignment of dashboards with the intended learning goals 75(Rodríguez Triana et al. 2014); and the orchestration challenges and time constraints teachers 76 commonly face in the classroom (Peiper 2008; Teasley 2017). It has also been reported that the 77 value of teachers' dashboards may depend on the degree to which teachers have been involved 78in their design (Holstein et al. 2018). Thus, if dashboards are to continue being introduced into 79CSCL classrooms, we need to gain a better understanding of the critical active role that data 80 International Journal of Computer-Supported Collaborative Learning

AUTHOR'S PROOF

may have on the teachers' decision-making process. To achieve this, it is critical to understand 81 teachers' data needs, the particular context of data usage, and how the design of the analytics 82 can be aligned with teachers' pedagogical intentions. 83

This paper presents the analysis of the perspectives of teachers who used a real-time 84 analytics tool to support the orchestration of a CSCL classroom during several sessions. A 85 longitudinal, authentic study was conducted with a handheld dashboard deployed in a multi-86 display collaborative classroom during one full academic term. The dashboard was designed, 87 configured, and deployed following a participatory process. The resulting dashboard allowed 88 teachers to manage the workflow and gain awareness of small group CSCL activities. It 89 showed real-time information about group participation and task progress: the current state of 90 the CSCL script; and a set of notifications informing teachers of students' misconceptions 91automatically detected. The study involved four teachers conducting 72 classroom sessions for 92ten weeks. Three applications that facilitate open-ended group tasks were used in both terms to 93 support: concept mapping, idea generation, and team meetings. The contribution of this paper 94 is the discussion of teachers' perspectives on real-time analytics in a CSCL classroom. This 95portrays both the promises and challenges of introducing new technologies aimed at 96 supporting orchestration and awareness. 97

Background

Classroom orchestration and learning analytics

There is an implicit overlap between learning analytics (LA) and the notion of orchestration 100that has appeared in a small number of research outputs (e.g. Dillenbourg 2015; Martinez-101Maldonado et al. 2016; Prieto et al. 2018; Rodríguez Triana et al. 2014; Verbert et al. 2013). 102The metaphor of orchestration was proposed to consider the real-time, multi-layered activities 103that teachers need to perform in the quite dynamic and unpredictable CSCL classrooms 104(Dillenbourg et al. 2009; Dillenbourg et al. 2011). Orchestration also includes the design of 105the learning tasks, and the degrees of freedom that teachers have when enacting the instruc-106tional plan (Dillenbourg and Jermann 2010; Tchounikine 2013). 107

Prieto et al. (2015a) provided a detailed analysis of the kinds of teacher's tasks that have 108been addressed by current orchestration literature. These tasks include: i) design and planning; 109ii) regulation and management; iii) adaptation, flexibility and intervention; and iv) awareness 110and assessment. It can be argued that the increasing use of technology in (and out) the 111 classroom can also increase the complexity of orchestration, particularly for already complex 112pedagogical approaches such as open-ended collaborative learning (Dimitriadis 2012). Or-113chestration technologies are aimed at alleviating such complexity by providing support to 114manage or to emphasise salient aspects related to the pedagogical or technical dimensions of 115the learning activity (Dillenbourg and Jermann 2010). 116

Emerging LA tools can be seen as a particular type of orchestration technology focused on supporting *awareness and assessment*. Wise and Schwarz (2017) and Stahl (2015) emphasised the opportunities that emerging LA approaches can bring to CSCL in years to come by providing new techniques to aid in the analysis of group processes and to support collaboration. For example, empirical work has suggested the potential active role of LA in CSCL research by augmenting the support that teachers can provide to students in group tasks (Van Leeuwen et al. 2014), increasing the monitoring capabilities of teachers in deploying CSCL

98

🖉 Springer

scripts (Rodríguez-Triana et al. 2018), and facilitating the assessment of simple constructs such 124as students' participation within a group (Xing et al. 2014). However, Wise et al. (2020) 125recently argued that the field still needs to generate understanding about how data traces can be 126mapped to higher-order CSCL constructs. Moreover, Tchounikine (2019) suggested that, if LA 127is going to play a key role in CSCL, this should be focused on supporting awareness and 128recommendation in ways that teachers and students can understand in order to make well-129informed decisions. The next subsections show how classroom data may play an important 130role in supporting teachers' classroom orchestration tasks. 131

CSCL dashboards in the classroom

Evidence of the growing interest in using dashboards and similar visual aids to support CSCL 133can be found in LA reports by Bodily and Verbert (2017) and Teasley (2017), with a 134noteworthy appearance of CSCL dashboards in a LA review by Schwendimann et al. 135(2017). A recent discussion paper on CSCL dashboards by Liu and Nesbit (2019) points at 136the critical importance of adopting an iterative, user-centred design approach to design for the 137complexity of CSCL awareness. User-centred approaches are common in CSCL (Kirschner 1382002) however, Liu and Nesbit (2019) warn that multiple forms of data can be captured in 139CSCL settings which creates an ample design space for data representation that needs to be 140explored. 141

Although the idea of visualising CSCL data has been explored by some researchers who 142have mostly focused on fully-mediated, online CSCL settings (see review in Liu and Nesbit 1432019), the idea of using dashboards to augment teacher's awareness in the physical classroom 144 is relatively new. Improvements in network technologies made the deployment of intercon-145nected desktop computers or Tablet PCs feasible and easy to achieve. These provided 146opportunities for teachers to conduct collocated collaborative tasks in the classroom (Zurita 147and Nussbaum 2004) as it was originally conceived by pioneering CSCL projects (Bruce and 148Rubin 1993; Nicolopoulou and Cole 1996). Subsequently, classroom dashboards started to be 149experimentally deployed (e.g. Kamin et al. 2009; Peiper 2008). Initial prototypes provided 150minimal information about the status of the software used by individual learners in real-time 151(Gutiérrez Rojas et al. 2012) or overviews of what learners did for post-class revision (Kamin 152et al. 2009). As emerging technologies that invite shared usage started to make their way into 153classrooms (for example, interactive tabletops, digital whiteboards and smart portable devices) 154more complex dashboard prototypes particularly tailored to supporting CSCL activity started 155to appear. For example, Do-Lenh (2012) presented a reflection tool that allowed the teacher to 156guide classroom reflection based on CSCL task progress visualisations generated from data 157automatically captured from small tangible tabletop devices. NumberNet, was also a multi-158tabletop environment for supporting CSCL activities (Mercier 2016). A dashboard presented 159to the teacher a list of correct or incorrect mathematical expressions automatically identified in 160the tables where students were working. More recent systems, based on tablet devices 161(Kreitmayer et al. 2013; Wang et al. 2015) and personal computers (Looi and Song 2013) 162also exploited data generated by the devices running a CSCL system to provide interfaces for 163teachers to monitor progress at a class, small group, or individual levels. 164

The interest in finding effective ways to communicate student data through visual representations for in-classroom real-time use is gaining momentum in CSCL. This is reflected by the proliferation of CSCL classroom dashboard ideas (see Tissenbaum et al. 2016) and current attempts to create classroom orchestration interoperability frameworks (e.g. Muñoz-Cristóbal 168

International Journal of Computer-Supported Collaborative Learning

et al. 2014; Phiri et al. 2016). Some off-the-shelf products are already incorporating certain 169elements of real-time monitoring. An example is Learning Catalytics (Schell et al. 2013) which 170provides visualisations to teachers about students' progress and their misconceptions while 171collaborating in the classroom using their own mobile devices. Monitoring tools such as 172Edquire (edquire.com) gather student usage information from local applications during a 173lesson which is then made visible to the teachers in real-time. Looking into the future, 174inroads have been made to go beyond dashboards displayed on a screen by embedding 'the 175dashboard' into the whole classroom by using mixed reality glasses (Holstein et al. 2018). 176

Learning analytics technologies for classroom orchestration

Most of the classroom dashboards mentioned above have been designed with the main purpose 178 of supporting the orchestration of CSCL tasks in real-time. In terms of workflow manipulation, 179they have provided different ways to control the pace of the class macro-script, for example, by 180moving the class through the activity as a whole (Looi and Song 2013; Mercier 2016; Wang 181 et al. 2015) or by allowing certain students advance at a different pace (Olsen 2017; VanLehn 182et al. 2016). Some of those dashboards also allowed to interrupt the execution of the task if 183 needed (e.g. Mercier 2016). A deeper review and discussion of these controlling functionalities 184 was conducted by Olsen (2017). Although control functionalities are important for orchestra-185tion, in this paper the emphasis is on data and the *state awareness* features that can play a 186critical role in the classroom. This is important because teacher-facing dashboards emerged as 187 one of the first direct applications of LA but the effects of their use still need deeper scrutiny 188 (Teasley 2017). 189

Based on the works discussed above, three types of data that can support orchestration in 190 the CSCL can be identified: 191

- The state or progress of particular groups. This has been tackled through the use of minimalistic representations such as progress bars (e.g. Do-Lenh 2012; Wang et al. 2015); 193 descriptive text (e.g. Wang et al. 2015) or by displaying the students artefact for whole class discussions (e.g. Do-Lenh 2012; Looi and Song 2013; Mercier 2016). 195
- The state of the workflow or time left according to the lesson plan. This has been achieved 196 by alerting the teacher of the time left through a timer (Kreitmayer et al. 2013) or a 197 timeline visualisation (Martinez-Maldonado et al. 2015a).
- The presence of mistakes or misconceptions in learners' artefacts. This has been explored 199 by presenting teachers with lists of errors automatically detected (e.g. Mercier 2016). 200

Most of these previous studies have been carried out under experimental conditions and during 201short periods of time. Progress has been done towards trying to understand how teachers can 202make sustainable use of dashboard technologies to orchestrate their classrooms. The closest 203work towards achieving this purpose is the FACT project (Cheema et al. 2016; VanLehn et al. 2042016). In this project, a similar handheld teacher dashboard to the one presented in following 205sections has been prototyped to be used in school classrooms. The authors of the FACT project 206discussed their experiences in terms of monitoring and orchestration as a result of a series of 207preliminary classroom trials with their toolset. Although not much empirical evidence from a 208teacher's perspective has been provided, these authors pointed at a number of critical design 209considerations that can make an orchestration tool successful by providing the right kind of 210support to teachers. They have also suggested the importance of providing just the right 211

225

amount and type of data to enhance teacher's awareness through functionalities such as stealth 212 assessment, notifications and information visualisations. 213

In sum, previous work CSCL dashboards deployed in the physical classroom suggest that 214data can play a critical role in augmenting teachers' awareness in terms of learners' activity and 215workflow management. However, most of the previous studies have been conducted under 216experimental conditions or involved authentic classroom interventions of short durations. 217From these studies, it still is unclear what would teachers' perspectives on data be after an 218extended period of use of such dashboards. The case study presented in this paper goes beyond 219previous work by generating understanding of teachers' perspectives after an extended usage 220of a dashboard in a complex, technology-rich CSCL classroom. 221

Design

This section first presents the classroom setup and the learning context in which the dashboard 223 was used. Then, the design principles and the features of the dashboard interface are described. 224

Classroom technical setup

The classroom in the current study endorses the vision of embedding computational capability 226into the classroom furniture. Interactive tabletops have been proposed as promising pervasive 227technologies that, if accompanied with the right pedagogical practices, can be used to support 228collaborative learning (Dillenbourg and Evans 2011; Higgins et al. 2011). Although tabletops 229have not reached a level of maturity needed to become a mainstream technology, they belong 230to a family of surface technologies which are already making their way into classrooms in the 231form of vertical touch displays and tablets. The teacher dashboard was deployed in a multi-232tabletop classroom. This is comprised of five multitouch tabletops that allow up to five 233students to collaborate around each of them (Fig. 1). 234

This learning space was used in the University of Sydney to conduct small-group activities 235for regular classes. The tabletops were enhanced with Kinect sensors facing down from the 236ceiling to add touch identification capabilities. This way, all actions performed by students on 237the tabletops could be differentiated. The three vertical displays in the room could be used by 238the teacher to display slides or for showing the final output of certain groups of students for 239discussion (e.g. see Fig. 2-left). Microphone arrays were located on each table, but due to 240expected classroom noise, the information captured by these was not presented to the teacher 241in real-time but analysed for research purposes. 242

Three tabletop applications could be used in the multi-tabletop classroom. These included: 243i) a concept mapping collaborative editor (Fig. 2-right); ii) a brainstorming system that 244supports rapid idea generation and clustering; and iii) a software development meetings 245*mediator* that allowed students to get access to their Trac sites (which include a wiki and 246issue tracking systems - trac.edgewall.org) from the tabletop. A software service, called the 247technical orchestrator, was built to control the devices and the apps. This served as a common 248operating application that sent commands to any plugged application. The tabletop 249applications (the concept mapping, brainstorming, and meeting mediator apps) implemented 250the actions internally. The orchestrator provided a common language of possible actions that 251the teacher could perform across applications. These included the ability to freeze the tabletops 252at will, to advance the tables to a next stage of the class script, to broadcast a text message to all 253

International Journal of Computer-Supported Collaborative Learning

Fig. 1 The technology-enhanced classroom where the teacher-facing dashboard was deployed

the tables, and to send the content of a particular table to the vertical displays. All these actions 254 were inspired by previous work on multi-tabletop classrooms (Do-Lenh 2012; Mercier 2016). 255 Data captured by the individual tabletop apps, the kinects, the microphone arrays, and the orchestrator were recorded into a common database server located in the classroom for real-257 time database queries to be issued by the dashboard and also to keep the data physically 258 contained in the classroom. 259

Learning context

The study was conducted as a part of two units of study coordinated by the same teacher: the261undergraduate unit Human-Computer Interaction and the postgraduate unit Pervasive Com-262puting, with a total of 108 and 42 students enrolled in each respectively. These were 13 weeks263long and had weekly 1-h tutorial classes where 20–25 students would work on small group264activities or on their capstone projects.265

Fig. 2 Left: a teacher leading the discussion on one of the students' final artefacts 'sent to the wall'. Right: one team of people illustrating how students could build a concept map at one of the interactive tabletops

Each unit had 6 and 2 tutorials respectively every week which were distributed among 266four teachers (TE1, TE2, TE3, and TE4, who taught 3, 2, 2, and 1 classes each, every week 267respectively). Each week, the *coordinator of the unit* provided the instructions to the 268teachers (tutors) with the topics, tasks and the macro-script that they were intended to 269enact. Students in both units were organised into small groups of 3-5 members from Week 2704. From this week, all classes were held in the multi-tabletop classroom and each group 271was assigned to one tabletop that they would use for the rest of the term. In each class, one 272or two out of the three tabletop applications (concept mapping, idea generation, and 273meeting support) were used in combination with other collaborative tasks such as group 274reflections and oral presentations. 275

By the end of the term, all teachers had experienced having access to the classroom data offered by the dashboard. These data included the tabletop activity logs, information about the status of the task or artefacts being built by students, the distance between these artefacts and the ideal solution defined by the coordinator, and the comparison between the class script 279 defined in the learning design and the pace in which each teacher enacted each phase of such script. 281

Design principles

Inspired by the notion of *social translucence* proposed by Erickson and Kellogg (2000), the dashboard was designed with the purpose of making some aspects of physical group visible. Socially translucent systems are those that make the interactions within a group of people visible to one another. A *translucent classroom* would then be one where evidence can be generated and shown to the teacher or learners to provoke reflection and sense-making, and generate the means for supporting the provision of feedback (fully automated or facilitated by the teacher).

A two-years participatory process was conducted with teachers to explore, design and 290 evaluate a series of analytics visualisations and functionalities that would be useful for making 291 CSCL classroom activity visible in real-time. This process included: 292

- i) Two lab-based design studies using real student data, consisted in presenting a set of lowfidelity (paper-based and digital) CSCL visualisation prototypes to 13 teachers in order to document their reactions and obtain feedback that could be translated into design changes (Martinez-Maldonado et al. 2011a, 2012); and
- Two authentic classroom pilot deployments with one teacher in two units of study during 297 two university terms (Martinez-Maldonado et al. 2015b, 2013).
 298

In the lab studies (Martinez-Maldonado et al. 2012), simulated data was used to identify the 299visual representations that would be more useful for teachers. In the classroom studies 300 (Martinez-Maldonado et al. 2013), the potential impact of the tool on learners was explored 301 by inspecting how students' solution changed as a result of the feedback provided by the 302 teacher. This paper goes beyond this previous work by presenting results of the sustained use 303 of the toolset by a number of teachers in authentic units of study. The paper is focused on the 304teacher's perspectives rather than on the tool validation as this has been the focus of our 305previous work. 306

Table 1 summarises the nine design principles that were identified. Four principles were307obtained from the lab-based studies (L1–4) and 5 from the classroom deployments (C1–5).308

International Journal of Computer-Supported Collaborative Learning

t1.1 Table 1 Design principles

- t1.2 L1-The visualisations that may be more suitable for real-time classroom use should allow rapid comparison among groups of learners by aggregating low-level indicators of group activity or automatically assessing a higher-order aspects of the group process.
 - L2-Teachers want to see data that can serve as evidence related to the task (the **epistemic domain**) and to the individual participation to detect free riders (the **social domain**).
 - L3-Teachers found it **hard to trust** on the output of a machine learning algorithm intended to compute the high-order aspect of collaboration. They preferred to make sense of the low-level data and find insights by themselves.
 - L4-Teachers indicated they did not want to see details in the classroom They preferred to get informed of **critical** events that occurred within a group.
 - eC1- The teacher wanted a way for the tabletop to **automatically assess the content of the students' task** because she could not do this in real-time. This would be helpful since she stated that she *"couldn't easily assess the quality of the students' task on the fly"*.
 - C2- The teacher asked for showing **text instead of graphical visualisations** because she thought the graph could be redundant if some descriptive text was already present.
 - C3- The teacher had to repeat the same tutorial several times with different students, thus she wanted to know how consistent she was performing here own **class script design**. In the future, she wanted to know how other teachers would be performing her learning design.
 - C4- The teacher wanted to **submit to the system an ideal solution of the task** before the class for accomplishing stealth assessment (automatically measuring the deviation of students' solution to hers).
 - C5- The teacher wanted to get notified of potential misconceptions within particular teams.

The dashboard interface

Q1

Figure 3 shows the final version of the dashboard used in the study. van Leeuwen et al. (2019) 310suggested three types of features that CSCL dashboards commonly contain, according to the 311 kind of support that is offered to the teacher: mirroring, alerting and advising. *Mirroring* 312 support consists in just showing information to the teacher for him/her to assess and 313 interpreting it. Alerting support consists in automatically detecting critical information from 314 the data and communicating it to the teacher. Advising support includes the previous two kinds 315of supports plus aiding in the interpretation for the teacher to take some action. As a result, the 316 final prototype features according to the kinds of support they offer, are presented as follows: 317

Fig. 3 The handheld dashboard's main components: i) placeholders for CSCL visualisations, ii) orchestration commands, iii) a visualisation of the class script, iv) a timer alarm of the current task, and v) notifications shown as rounded squares around the CSCL visualisations of certain groups (green for positive and red for negative notifications)

A placeholder for CSCL visualisations or textual information of each group in the 318 classroom (mirroring support) Following the human-centred participatory process, the in-319formation about each small group shown to the teachers was selected based on the preferences 320 of the teachers in previous experimental and classroom experiences. At the same time, the kind 321 of information presented is partly limited to the kind of data that the technology available in the 322 classroom could reliably capture. For example, although some basic conversation patterns, 323 such as turn-taking and overlapping, would contribute to understanding some aspects of 324collaboration (Stahl 2002), and microphone arrays located in each table would ideally auto-325matically detect those (Martinez-Maldonado et al. 2011b), the classroom is too noisy. Current 326 automated solutions have only worked well thus far in experimental settings (Chandrasegaran 327 et al. 2019). 328

Hence, following the principles L1 and L2 learnt from the lab studies, the dashboard was 329configured to present information (mirroring) about *individual participation* (see Fig. 3-i and 330 Fig. 4-left, spider diagrams) and group task progress (see Fig. 4-right, concentric circles 331 representing the size of the group solution and extend of connectedness of ideas in the concept 332 map or brainstorming task). Individual participation within a group has been used as a basic 333 indicator to identify potential collaboration issues, such as marginalisation (Prinsen et al. 2007) 334 and the presence of "ghosts" or "free-riders" (Hämäläinen and Arvaja 2009), in CSCL 335 contexts. Showing task progress of multiple groups has also been a basic construct shown to 336 teachers when monitoring multiple groups (Do-Lenh 2012). In the preliminary lab studies, 337 teachers explained they would not trust in automatically generated assessments of collabora-338 tion (L3) and that they would not like to see many details about the groups (L4). 339

The visualisation of group *task progress* (Fig. 4-left) was, in some classes, presented to 340 teachers just as text, removing the concentric circular areas that represented the 'size' of the 341 student's artefacts (Fig. 5). This visualisation was tested to follow up on a suggestion by the 342 teacher who participated in our preliminary classroom pilot studies who stated the following: 343 "Maybe instead of having a graph we could have a table with this information: number of 344

Fig. 4 Visualisations about individual participation (left – spider diagram of the amount of touch interaction per student) and group task progress (right - represented as two concentric circles whose area represents the size of the group solution and the distance to the teacher's solution for the outer and inner circles respectively)

International Journal of Computer-Supported Collaborative Learning

Fig. 5 Visualisations about task progress: graphic (left) and text-based (right) versions

concepts created by the group and the links that are relevant to the case study. There is no point 345 of having the same information repeated in text and graphically" (principle C2). 346

A set of orchestration commands for controlling classroom displays and applications A347 green button labelled as "START" at the top-left of Fig. 3-ii allows the teacher to load the 348 CSCL script at the beginning of the class. The button "Next Phase" advances all the tabletops 349to the next phase in the script (e.g. negotiation phase, instructions phase, idea generation phase, 350etc.). The buttons "Block Tabletops" and "Unblock Tabletops" allows the teacher to stop the 351script, disable the touch interaction of the touch screens and dim the screens in case s/he 352 needed to give particular instructions or interrupt the flow of the script to provide feedback at a 353 class level. 354

A CSCL macro-script visualisation (mirroring and alerting support) As with the other awareness functionalities, during the previous pilot studies, the teacher highlighted that she "usually didn't stick to the initial plan across classes as the pace of the groups in each class was different, sometimes needing to take more time in certain tasks or even skipping things [she] originally planned" (principle C3). This motivated the provision of information (mirroring) about the enactment of the class macro-script as a timeline and an alarm (alerting) for the teacher to be aware of the time spent in each phase of the script (see Fig. 6-left).

Fig. 6 Real-time feedback on the teacher's enactment of the learning design in the form of a timeline visualisation (left) and an explicit timer alarm (right)

A CSCL macro-script (Dillenbourg and Hong 2008) can be defined in XML format by the 362teacher or a researcher. This contains the sub-tasks that should be executed by each tabletop 363 application, and their intended duration according to the learning design. Once loaded, the 364macro-script is executed by the classroom ecology under the control of the teacher, with the 365 flexibility for the teacher to alter the initially planned timings. This flexibility is provided, as 366 the actual events in a classroom are not predictable (Dillenbourg et al. 2018). The class script 367 timeline is shown as a progress bar at the top of the dashboard (Fig. 3-iii and Fig. 6, left). It 368 shows a phase in dark red (e.g. initial instructions and idea generation in Fig. 6-left) if it took 369 longer than what was planned in the original script (e.g. phases instructions and idea gener-370 ation). Those phases enacted below the allocated time appeared as (pale) blue sections of the 371 progress bar. 372

An alarm that notifies the teacher in case the current phase is taking longer than373planned (alerting support - principles C3 and C5)Beside the coloured sections in the class374script timeline, a rounded square located at the bottom-left of the dashboard shows the time375that the current phase is taking (Fig. 3-iv). The colour of the square changes from black to376bright red once the phase has taken longer than planned (Fig. 6-right).377

A set of notifications automatically triggered when critical events configured by the coordinator occur (advising support) Notifications were provided as a more prescriptive means for teachers to be aware of quality aspects of the group task. The teacher who participated in our preliminary classroom pilot studies said that she "couldn't really identify students' misconceptions since it would take a long time to look at each map, but it would be good for the system to point at suspicious statements students create in the tabletops" (principle C1).

Two types of notifications were created. The first type of notification was triggered when 385 misconceptions were automatically identified in a group's table by matching the students' 386 solution with a list of common misconceptions pre-defined by the coordinator of the units of 387 study (principle C4). The notifications appeared as a red or green square around a group's 388 visualisation (see Fig. 3-v). The teacher had to tap on the visualisation to read the details of the 389 notification. Figure 7 shows the text generated for two examples: a 'negative' (red) notification 390of a misconception detected by the system in the blue table (left), and a 'positive' (green) 391notification informing the teacher about the progress of the red group (right). 392

Study

394

Based on the current CSCL dashboard developments presented in the Background section; the395gap identified in the literature regarding the lack of analysis of the effects of the extended use396of teacher-facing dashboards (Teasley 2017) and CSCL dashboards (Liu and Nesbit 2019); and397the lessons learnt from our own pilot studies, the aim of this study was to understand the398teachers' perspectives on the orchestration and state-awareness functionalities of the real-time399analytics dashboard after extended use.400

The following sub-questions serve to investigate the different features of the dashboard: 401

- RQ1: what are teachers' perspectives on having real-time access to CSCL visualisations? 402
- RQ2: what are teachers' preferences in terms of interpreting visualisations versus text?
- RQ3: what are teachers' reactions to the notifications?
- RQ4: what are teachers' perspectives on the scripting visualisation and alarm?
- RQ5: what are teachers' perceived advantages and challenges in carrying a handheld device?
 406 407

Illustrative episode of the dashboard usage

The following episode that occurred during the last class of the unit of study Human-Computer 409Interaction (in Week 13) illustrates how the teacher used the dashboard. In the following 410excerpt (Table 2), the groups of students had already been working for several minutes on a 411 concept mapping activity. They were asked to build a concept map that reflected a number of 412 usability methods in the context of a usability study they had to plan during this class. This 413 episode was recorded by following the teacher's moves in the classroom with a video camera 414 during her class. The video was transcribed, and the dialogue excerpts were enriched with 415descriptions of the teacher's and students' actions. This teacher's class was randomly chosen 416 amongst all the classes available and also because all students in this class consented to be 417 video recorded. 418

Due to practical and orchestration limitations, not all the classes could be recorded 419 in this way since *all* students had to give permission to be video recorded (including 420 signing an ethics consent form). It was also not practical to follow all teachers with a 421 video camera in all their classes. Thus, this example is limited to illustrate how 422 teachers could use the dashboard during their classes. Whilst this example focuses 423 on a concept mapping class, other collaborative tasks that students performed included 424 brainstorming and project meetings. 425

Analysis

The brief episode described in Table 2 illustrates the complex orchestration tasks 427 carried out by the teacher and the influential role that the dashboard can have. A series 428 of semi-structured individual interviews were conducted with the four teachers in week 429 7 (the middle of the term) and week 13 (the end of the term). The duration of the 430 interviews was from 40 to 60 min. In each interview, teachers were asked to describe 431 their own experience regarding each of the functionalities and visualisations of the 432 dashboard. The structure of the interviews corresponded to the research questions 433

Table 2 Illustrative episode of the dashboard usage

(RQ1-5) listed above. Teachers were asked to reflect on their experience in: i) having 434real-time access to CSCL visualisations in the classroom; ii) making sense of visual 435versus textual information; iii) reacting to automated notifications; iv) having real-time 436 access to a scripting visualisation and an alarm; and v) in carrying the handheld device. 437 All interviews were fully transcribed. A total of 115 reflective statements were identi-438fied (these are reflections, composed by one or more utterances, that talk about one or 439more dashboard functionalities, design requirements, or orchestration activities). These 440were clustered into themes corresponding to each RQ. The next section presents the 441 results of this analysis. 442

International Journal of Computer-Supported Collaborative Learning

Table 2 (continued)

The teacher stays at the **Black table** for about 1 minute in total, just looking at what students are saying and doing with their concept map while holding the dashboard (see Figure E).

Then, she looks at the dashboard more carefully and decides to go to the **Yellow table**. As shown in Figure F, the dashboard shows the smallest circles for tables **Yellow** and **Black**, followed by the **Red** and **Blue** tables, at this exact moment. This may indicate these two groups may be falling behind compared with other groups in the class.

The teacher goes to the **Yellow table** and listens to students' conversation (see Figure G). Then, she decides to start a conversation: Teacher: *Have you gotten to the design of your user test*?

- L_Yellow1: Yes, and we got more things than what we can test with users.
- Teachers: How many users do you think you would need?
- L_Yellow2: About 50 users. We need six for a usability test.
- L_Yellow1: Then, we need 10 for this other system. And we need 35 for the following prototypes.

Teacher: This sounds fine, just make sure you start adding all this to your concept map.

The Teacher walks back to the **Black table**. However, before engaging with the learners in that table, she notices that there is a notification coming from the **Blue table** (see Figure H) pointing at the presence of a few misconceptions automatically detected (see detail in Figure I).

The teacher walks to the **Blue table** instead and engages with the students as follows:

Teacher: I think you have some non-user methods marked as user methods.

- L_Blue1: We have been moving things around, and also deciding on the number of users we need.
- Teacher: Yes, but I don't think you need users for *cognitive* walkthrough.
- L_Blue2: Oh! That one is in here. We think this is a user method
- L_Blue1: Or at least, that's what we decided.
- Teacher: and what about UMUX?
- L_Blue3: We have it here! [pointing at another section of the concept map at the tabletop].

(...students start to negotiate their claims made in the concept map but, eventually, the teacher makes them see why these propositions were wrong)

Results

Teachers' perspectives on the CSCL visualisations (RQ1)

Teachers were provided with the visualisations about group task progress and individual445participation. The following reflection illustrates how a teacher interpreted the first visualisa-446tion of task progress (e.g. Figure 4, right):447

[the visualisations] were useful, you could tell by looking at them that this group449[pointing at a visualisation in the screen], the 'black group' was far behind at that450moment. Sort of I would know that I should go and help them. Sometimes I couldn't451help them, so I couldn't make them look better in the dashboard, but at least I knew what452I was dealing with in that class. In this case, I wouldn't have worried about other groups453as much, but I would still go and confirm that they were fine. (Teacher TE1)454

This suggests that the tool invited the teacher to find out more about what is going on with a455particular group. As teachers may find hard to assess each group's solution "on the fly",456providing task-related information to teachers in real-time may have enhanced awareness. For457this teacher, it was up to her what to do with these data.458

Other teachers were similarly optimistic about this type of visualisation, since it helped 459 them in "being able to quickly compare groups at a glance" (TE3) and "making better 460 decisions in later stages of the class" (TE1). However, they also recognised the limitations 461 of the data provided and the need for alternative sources of information to get a better picture 462 of what was happening with each small group. For example, TE2 summarised this as follows: 463

It was really good to see how groups were progressing straight away. I could quickly stand in the middle of the classroom and get a sense of what groups were making progress and which were not. However, it didn't give me any information about who was doing the work, their strategies, or if there was fair collaboration. 467

This points out at the need for other sources of evidence that would allow the teacher to make 468 better assessments of the groups in the classroom and decide which group may need more help. 469

TE2 also suggested the following "It would have been good to have collected information 470about talking too, but I am not sure if this would be feasible to be collected in the classroom". 471 This teacher justified the importance of knowing about this dimension of interaction as 472follows: "maybe the people who were doing all the talking wouldn't be adding ideas 473physically but this way I could have a better picture about identifying those individuals". 474This kind of commentary was expected as it is in line with the results of our lab studies, in 475476which presenting differentiated speech summaries along with logged individual contributions in a single visualisation was highly valued by teachers. Although audio levels were collected 477 through the microphone arrays located in each table in the classroom, the quantitative measure 478479of speech in the classroom is still technically challenging in terms of accuracy (e.g. filtering the classroom 'noise') and unobtrusiveness. Some recent work in this area is attempting to 480 automatically capture turn-taking patterns in the classroom (Noel et al. 2018). However, 481 correctly differentiating group members' voices from noise coming from other groups still 482needs further research and development work to be able to make reliable assessments. 483

TE2 and TE3 also highlighted the value of summarised information but pointed at the lack 484 of information of individual contributions for the *task progress* visualisation: 485

International Journal of Computer-Supported Collaborative Learning

It was really good to see who was stuck and who was doing really well, but not much 486 information about individuals, which I don't know if it is really useful on-the-fly. Maybe I can 487 just do by sitting next to them for a bit to get a good sense of who is leading the work. (TE3). 488

This was compared with the reflections on the visualisation of *individual participation*, 489 which depicted the names of students seated at each table (see Fig. 4, left). The same teacher 490 (TE3) valued that through this second visualisation she "could [for example] see that two 491 students were really active, but one was not active at all". At the same time, another teacher 492 recognised the challenge of processing the details in real-time. TE4 described his classroom 493 experience and suggested design changes that could make the visualisation more effective: 494

In the classroom, it was really hard to notice the student names. I just looked at the shapes. 495 Maybe only highlighting particular students in need would be useful. If I knew this information I would go particularly to talk with that student and try to motivate him [her] to express some ideas. 498

This suggests the potential need for a design adjustment in which teachers could be able to select what visualisation to see or a visualisation that includes both types of information about participation and task progress. 501

In sum, the CSCL visualisations presented in the dashboard to the teachers during an 202 extended period triggered reflections and ideas for further development of the tool. Interestingly, teachers understood the value but also recognised the limitations of the role of data in the classroom. Interestingly, they highlighted how the data can play an important role in their pedagogical practice but also that the way in which information can be explored or selected for rapid sensemaking is critical. This was explained by one of the teachers as follows: 507

I had one girl in my tutorials that didn't talk much. I remember looking at this graph [the 508 individual participation visualisation] and realising there was someone who had not added 509 anything. It is just that I didn't read her name, but I knew who she was from the actual tabletop 510 interface which had the ideas colour-coded. I went there, and I remember she generated one 511 idea while I was there. She was there doing nothing just looking. I think having this 512 information more explicit would have been very helpful (TE3). 513

This suggests that further work is critical for creating CSCL visualisations that explain potential issues that the teacher should look at rather than just presenting information that invites the teacher to analyse the data on the fly. This is in line with recent research in the area of learning analytics suggesting that educational visualisations should be explanatory rather than just exploratory (Echeverria et al. 2018). 518

Teachers' preferences on interpreting visualisations versus text (RQ2)

As expected, teachers generally preferred the graphic version since "it is easier to compare 520sizes" (TE3), whilst for the text version, it "takes more time to do calculations to compare the 521task progress" (TE3) or simply "all numbers cannot be read at the same time making it hard to 522figure out which group is progressing more" (TE1). This is aligned to foundational information 523visualisation literature (Treisman 1985) which points at the benefits of visualising information 524using graphs instead of text to take advantage of human's preattentive processing (visual 525properties are processed by our sensory memory without our conscious thought) (Yoo et al. 5262015). However, as argued by Knaflic (2015), under certain conditions text itself may be more 527effective than graphs. 528

Teachers reflected on learning situations where they preferred the text version. TE3 529 explained one of these cases as follows: 530

the text version was useful for the task where students were asked to only link 10 ideas532together. In this way, I just looked at the number of linked ideas. The linked ideas text533was very simple and was presented in big fonts, bigger than the graphic version so it was534easier to interpret linked ideas through this visualisation. I think it all depends on the task535students were doing.536

This confirms that the request by the teacher in the pilot studies made sense for the particular 537kind of CSCL task being enacted in the classroom. TE3 also requested design additions that 538could direct the teacher's attention and that could be applied to the graph or to the text 539versions, such as "a marker indicating which team had the max or min number of ideas or 540concepts". In short, simply showing text should not be dismissed as an option to communicate 541data to the teacher in the classroom but it depends on the intentions of the learning design. Still, 542graphs can communicate information more rapidly, especially when comparing aggregated 543data. 544

Teachers' reactions to the notifications as narrative feedback (RQ3)

The 'positive' notifications were made available to teachers in the second part of the term as a 546 response to one of the teacher's comments at the middle of the term: 547

the interface sorts of guides you towards the students who may be not doing so well. It549would be great if the interface can also emphasise when students are doing alright. I550would notice that if I hear them talking about other stuff or if they look bored, but it551would be also nice to confirm it from the data you are already collecting (TE1).552

Teachers in the study acted as a result of reading both types of notifications as it was 553 commented by one of the teachers as follows: 554

I think both types of notifications were useful. The red ones are useful because I can easily identify if there is a problem in a group and try to fix it. I can tell the group, as soon as I can see it, that there is some problem, so they can immediately take action or make some suggestions, so they can figure out what is the problem and learn something. Although the 'green' notification had the lowest priority, I still used to go to the group and let that group know that they were progressing positively (TE3). 556

Other pedagogical strategies emerged over time as teachers became more familiarised with the notifications. For example, TE4 used the notifications to provide delayed feedback at a class level. This was described by the teacher as follows: 564

If all the groups eventually had the same problem, I could stop the whole class for a565short time and explain to the whole class any misunderstanding. Or at the end, in the567discussion phase, I could say for example: all of you had this problem. For the 'green'568ones I preferred to provide them immediate feedback to encourage groups to keep569motivated.570

The information provided by the notifications about misconceptions could also be used to 571 provide better feedback to particular groups as described by TE3: 572

International Journal of Computer-Supported Collaborative Learning

AUTHOR'S PROOF

Because at the end students had to share their solutions with the class, I could give them573more adequate [delayed] feedback to that group not just from their explanation but from575what it happened during the whole activity as informed by the notifications. I could even576have skipped interventions during the activity and still be aware that some problems577existed. However, I also used the notifications during the tutorials to provide immediate578feedback.579

Interestingly, TE4 used the positive notifications not only to encourage students but also to 580 make them notice that she was aware of their progress. This was phrased by the teacher as 581 follows: 582

I was using the 'green' ones to motivate students but also to make them see the benefits583of using the tabletops to make them positively accountable, so they can feel that I can see585what they are doing. For example, one student even asked me surprised: how do you586know what we are doing? For them, this would be a positive motivation since they know587that I can have an idea of what they are doing even if I attend other groups. I think in this588way they were more interested in continuing with the activity.589

In regard to the negative notifications, TE4 explained that sometimes the misconception 590automatically identified as wrong, could be acceptable in the context of the solution that 591students were constructing or because of slightly different wording they were using. This was 592explained by the teacher as follows "If I identified there was a potential wrong proposition I 593would go to the table and try to help them fix that by talking with them. In a couple of cases, 594two groups convincingly justified why their statement was correct". The examples in this 595section show that both types of notifications were not used just to do a summative assessment 596of students' solution but rather used as a tool to drive attention and prompt dialogue. 597

Teachers' perspectives on the scripting visualisation and alarm (RQ4)

In general, teachers reacted positively to having access to information about the intended 599design and the enactment of the class script. For example, TE2 explained the following: "it 600 makes it much easier to know how I am going with the script rather than spending all the 601 time and realising at the end of the tutorial that we have to skip the last tasks that were in 602 the plan". Another teacher (TE3) explained how this information helped her figure out 603 when she had to compensate the duration of certain tasks: "for example, if I could see 604 many red sections (over-timed tasks) I knew I had to consider that for the current stage". 605 This suggests how the real-time access to this information helped her in managing the time 606 of the whole class. 607

At the same time, teachers pointed at certain limitations. The first is not necessarily 608 associated with the toolset or the visualisations but with the flexibility needed to make their 609 changes to the learning design more permanent. Although the same learning design was 610 provided to all the teachers, they all mentioned that commonly, the timing of the phases 611 (proposed by the coordinator of the unit of study) had to be adjusted. TE2 explained this as 612 follows: "In terms of usefulness I think this functionality was awesome, but in terms of the 613 timing configuration it may improve. Obviously, this has to be with the plan given by the unit 614 coordinator rather than the technology itself'. TE4 suggested a possible local solution to carry 615local knowledge across her own classes as follows: 616

After teaching the first class I knew that for some tasks we needed more time and for 618 others we could go through faster. It would be great if the dashboard lets me modify the 619 original plan myself after the first class. Based on this I could also get an idea early on to 620 skip some bits if I was getting rid of time. 621 This suggests that making more permanent changes to the learning design can potentially 622 enhance the effectiveness of this tool in the classroom. 623 Notably, a couple of teachers requested slightly more intrusive ways to alert them if they 624 were spending too much time in a certain task. TE2 stated the following: 625

I could allow the interface to warn me by beeping or vibrating if I have been talking too 626 much with a student. Sometimes this happened in some classes. The students would also 628 notice we are getting rid of time, so they could focus on their work and let us move on. 629

Another teacher explained that she wanted to keep awareness of certain alarms even if she was not looking at the dashboard interface: "I stopped looking at the screen when it became obvious what the next phase was or if I was talking with a student, but I still wanted to be reminded if I was over time" (TE1). 633

In short, presenting visual information of the enactment of the class script can be useful for teachers but the system needs to be flexible for them to adjust the class design on the fly or to suggest more permanent changes to be carried to the following classes. 636

Advantages and challenges in carrying the handheld device (RQ5)

Although presenting the dashboard on a tablet allows the teacher freedom of movement around 638 the room (Mercier 2016), carrying a handheld device while teaching can produce fatigue over 639 time. In previous studies where tablets were handed to teachers for orchestration, including our 640 own pilot studies, teachers did not continually use the device during a full term. In our 641 longitudinal study, similar potential issues were identified, but also advantages. Besides 642 fatigue, one of the clear shortcomings of showing the dashboard on a handheld device is that 643 teachers "cannot use their hands, making it hard in times when [they] need, for example, two 644 hands to revise papers or other devices that students want [them] to look at" (TE4). TE1 also 645 commented the following: "It was slightly annoying that I have one hand occupied. Students 646 sometimes wanted to show me their prototypes so it was a bit hard to keep holding the 647 dashboard on one hand and their laptop on the other. Having said that, I still prefer access to 648 that data". 649

Possible solutions were hinted by teachers, for example, TE3 described her strategy to use the 650 dashboard only when needed: "I would also put the dashboard down when I had a very good 651 sense of how the class was going and what things I had to deal with. I still wanted to come back 652and see how well I was doing with time". TE4 suggested that she would be happy to carry the 653 dashboard on her mobile, but that she definitively did not want it shown in a public space that 654everyone can see as this would be distracting for students: "I prefer that the teacher is the only that 655 can see this information" (TE4). TE1 summarised the advantages of having the dashboard 656 available on a mobile device as follows: "It's good having the tablet because you decide when 657 to check visualisations no matter where in the classroom you are", however, alternative solutions 658 can be found. Ongoing work is exploring the feasibility of using augmented reality lenses to get 659 the right balance between portability and availability (Holstein et al. 2018). 660

662

663

International Journal of Computer-Supported Collaborative Learning

Overview of the results

Table 3 summarises the key insights obtained from the interviews with teachers.

Discussion

Kaendler et al. (2015) proposed that teachers need to have a set of competencies to effectively 664 foster student learning in CSCL environments. The most relevant of these competencies 665 related to the design of dashboards to support teaching in CSCL classrooms is that of 666 *monitoring* student interactions. Visual and textual means to augment the monitoring capabilities of teachers are not new within CSCL (see classic work and review by Soller et al. 2005). 668

Table 3 Summary of results	
Research questions	Key insights
RQ1: what are teachers' perspectives on having real-time access to CSCL visualisations?	 Visualisations of group <i>task progress</i> and <i>individual participation</i> helped teachers to quickly compare groups and identify those groups that needed closer attention. Teachers requested more specific information such as automatically highlighting top contributors or particular students who needed help. Teachers requested information about speech content. Some teachers suggested more flexibility for them to configure what information to show in the dashboard and explanatory visualisations that automatically highlight potential issues found in the data.
RQ2: what are teachers' preferences in terms of interpreting visualisations versus text?	 Teachers preferred to interact with graphs instead of text while using the dashboard in the classroom. Text can be used to communicate specific information (e.g. insights from the data or numeric values) that teacher can use to provide tailored feedback to students.
RQ3: what are teachers' reactions to the notifications?	 Teachers used both types of notifications (of detected misconceptions and positive progress) to provide immediate feedback to specific groups. Some teachers used the notifications to gain awareness of the state of the class and provide delayed feedback on commonalities across groups.
RQ4: what are teachers' perspectives on the scripting visualisation and alarm?	 Both the visualisation and alarm of the class script allowed some teachers to adjust the enactment of the class script on-the-fly. Some teachers indicated it was easier to identify current issues with the calibration of the class script to be considered for re-design. Some teachers suggested more intrusive ways to be notified about critical issues such as spending too much time in specific tasks or with particular students or groups
RQ5: what teachers' perceived advantages and challenges in carrying a handheld device?	 Teachers appreciated making the dashboard available through a personal device for private use. Some teachers preferred to have both of their hands free, but still wanted to have access to the data. Some teachers suggested using their mobile phones instead, or other means to endorse both portability and data availability.

Yet, different visualisation techniques keep being used to track individual participation within 669 a group (e.g. Sirbu et al. 2019), and group progress (Noguera et al. 2018), mainly in online 670 systems. Regarding mirroring and alerting about the enactment of the CSCL script, not many 671 real-time visualisations exist (Mangaroska and Giannakos 2018). In a way, this means that the 672 design of the dashboard itself is innovative as it provides live information about various of the 673 CSCL classroom in ways that have not been possible before. However, we cannot understand 674 teachers' and learners' practices and needs that can be addressed using data if those are not 675 analysed over time (Brown 1992). The longitudinal study presented above allowed us to 676 identify some tensions in the way teachers used the dashboard, which can become into sources 677 of inspiration for innovation and design. It is expected that more learning analytics innovations 678 will keep making its way into CSCL environments (Liu and Nesbit 2020). This means that a 679 design stance strongly grounded in learners' and teachers' needs will be essential to ensure the 680 alignment between, on the one hand, emerging data-intensive technologies and, one the other 681 hand, best pedagogical practices and foundational CSCL theory. 682

The notion of *Collaborative Learning Analytics* has been proposed to explain the natural 683 convergence between learning analytics and CSCL (Wise et al. 2020). This has pointed at the 684 need to map from low-level data to pedagogically meaningful group constructs that make 685 sense to non-experts (Echeverria et al. 2019). The information provided by our dashboard 686 included basic constructs related to the progress of the task indicated by the size of the 687 students' solution, the extent of participation within each group, notifications about the 688 correctness of the content of students' artefacts, and the extent to which the teacher follows 689 or deviates from the original plan. Yet, higher-order issues were discussed by the teachers who 690 experienced the use of the dashboard for an extended period of time. Although some of these 691 evidently go beyond what our handheld dashboard could offer, they shed light on aspects that 692 need further exploration in authentic CSCL dashboard design. In the following lines, these 693 issues are discussed. 694

The natural incompleteness of classroom data The data made available to teachers for real-695 time consumption were incomplete since not all aspects of the learning and collaboration 696 process could be automatically captured. Still, teachers were provided with information which 697 they commonly do not have to be able to make their own decisions. However, the incom-698 pleteness of the data can potentially lead teachers to make erroneous assumptions (Bienkowski 699 et al. 2012), particularly since the visualisations shown to them do not embrace the complexity 700 of collaborative learning (van Leeuwen et al. 2015). Slade and Prinsloo (2013) identified that 701this situation may easily make the data available in the classroom vulnerable to misinterpre-702 tation and bias. In our longitudinal study, teachers were enthusiastic about the data but also 703 pointed at the need for more sources of evidence to be able to have a better picture of what 704happened in each small group. In a dystopian scenario, there is the potential risk that a teacher 705may want to consider the visualisations of individual participation that we showed in the 706 dashboard as the basis for assessment of performance. Hence, this paper must be seen as one of 707 much more CSCL work that is needed to start understanding how data traces can most usefully 708 serve to augment teachers' awareness in CSCL physical spaces. This has been proposed as one 709 of the top priorities for CSCL by Wise and Schwarz (2017). 710

The trade-off of immediatenessIn our study, all teachers mentioned that they tended to take711immediate action after receiving a notification. In some cases, teachers decided to delay the712feedback to gain a better understanding of what was happening in the classroom and provide713

International Journal of Computer-Supported Collaborative Learning

well-informed feedback to all the students. While the provision of immediate feedback may lead to 714 better learning outcomes (Hattie and Timperley 2007), there is a risk that teachers may take 715corrective actions too soon, based on partial representations of the students, or without letting 716 students tackle the problem by themselves first. The trade-off of providing immediate or delayed 717 feedback has been explored in CSCL (Gweon et al. 2007) and teamwork (Walton et al. 2014) 718 settings with varied results strongly depending on task settings, groups, and pedagogical ap-719proaches. Ultimately, a teacher's pedagogical stance is critical, and its effects depend on the 720 learning situation. For example, Loibl and Rummel (2014) found that delayed feedback is quite 721 effective if accompanied with pedagogical strategies such as comparing and contrasting students' 722 outputs. The ethical dilemma here is that teachers cannot afford not to use classroom data anymore 723 if these data can be readily available (Slade and Prinsloo 2013). A critical question is: how to 724 effectively use such data for pedagogical purposes? Further research needs to be done to develop 725the technological means and the pedagogical practices to find the right balance between the 726 provision of immediate or delayed feedback based on evidence depending on the context. 727

The risk of increased orchestration load The risk of overloading the teacher with informa-728 tion is evident. There may be a well-intentioned attempt of making many aspects of the 729 classroom and students' activity visible. Too much information or a poorly designed dashboard 730 can increase the orchestration load of the teacher (van Leeuwen 2015). The concept of 731 orchestration load has been defined as the effort that the teacher needs to put in coordinating 732 multiple learning activities (Prieto et al. 2015c). But the risk is not only in the amount of 733 information but also the type of visual encodings used in a CSCL analytics tool that may 734impose more *cognitive* load (Card et al. 1999). Thus, introducing a new analytics tool in the 735 classroom may increase the orchestration and cognitive load of the teacher. This can be 736 addressed through effective Information Visualisation design (Spence 2001) and by trying to 737 understand how teachers would gain insights from specific data representations (Yi et al. 738 2008). Emerging multimodal analytics approaches to quantify orchestration load are emerging 739 (Prieto et al. 2017), but much work still needs to be done to measure the impact of a learning 740analytics dashboards on both orchestration and cognitive load. 741

The trade-off of access and disruption In our authentic classroom experiences, data played a 742 major role in the classroom dynamics. As stated by the teachers, different actions were triggered as 743 a result of looking at the visualisations, notifications, and alarms. The coordinator of the unit of 744 study also changed her behaviour as she created more explicit CSCL scripts to be visualised by the 745dashboard, which is not necessarily a common practice. In sum, we provided enough evidence 746 that the data given in real-time to teachers had the potential to *disrupt* the orchestration of the 747 classroom. Data became another component that needed to be orchestrated with the support of the 748 research team. The trade-off here is that data and real-time analytics can be disruptive as they can 749 drive the teacher to perform actions that may (negatively or positively) affect the learning process. 750Although any computer system can disrupt the CSCL (Bannon 1995) or orchestration processes 751(Dillenbourg et al. 2011), the role of data in the CSCL classroom can directly influence important 752decision making processes that can strongly shape how collaborative learning unfolds (Rodríguez 753Triana et al. 2014). The positive or negative effects of this disruption would depend on factors 754such as the interpretation of data and the pedagogical actions taken as a result. In our classroom 755 experience, it was up to the teacher to decide on the orchestration actions taken after each 756 interaction with the dashboard. Further work needs to be done to understand the impact of each 757 of these interventions on learning. 758

Future work There is an evident trade-off between generalisability and contextualisation since the 759data capture was facilitated by the specific type of technology used: large multi-touch tabletops 760enhanced with kinects to differentiate students' actions. This setup is hard to replicate in conven-761 tional classrooms even if similar hardware, such as vertical displays, are used (Clayphan et al. 2016). 762 Nonetheless, results from the analysis of teachers' perspectives are already informing the next round 763 of iterative improvement and implementation of the functionalities of the dashboard. For example, 764current work in this line of research is focusing on providing teachers with timer alarms to alert them 765about the time spent at each group in regular CSCL classrooms by using proximity sensors (Author 766 2019). Similar visualisations of group activity are being co-designed with both teachers and students 767 to be used in classrooms in healthcare education in which multiple teams work around patient beds 768 (instead of tabletops) as they are monitored by a teacher (Author, 2018). As sensing capabilities are 769 rapidly improving, the lessons learnt from teachers' perspectives on the dashboard use are serving to 770 define the features of the next generation of CSCL classroom dashboards, that include visualisations 771of conversation patterns, physiological aspects, localisation, and differentiated actions to be used by 772 both teachers and students (see preliminary work in Echeverria et al. 2019). 773

Conclusion

774

As technology advances, particularly in the area of pervasive computing and multimodal 775 sensing, capturing traces of collocated collaboration activity, which has been considered 776 ephemeral and invisible to computational analysis, is becoming feasible. This will open new 777 opportunities to support collaborative learning and instruction in collocated, complex learning 778 spaces. However, to gain a better understanding of, and effectively support learning in CSCL 779 classrooms, we need to identify how data may interplay with CSCL pedagogy and theory. 780Understanding teachers' perspectives after they use learning analytics innovations during an 781 extended period of time is critical to designing interfaces that can be orchestrated by the 782teacher and that can effectively support their monitoring needs. In this paper, we discussed the 783 tensions highlighted by teachers as a result of their authentic experience in the context of using 784 real-time data to orchestrate a multi-tabletop classroom. As illustrated, what a teacher chooses 785to do with information is highly personal and often depends on factors such as the dynamics of 786 the classroom, the students attending the class, the lesson plan of the day, and the teacher's 787 skills and experience. We envisage that, as emerging sensing and interactive technologies 788 mature, it will become even more feasible to build systems that support teachers, from 789mirroring information to communicating insights effectively, in the physical CSCL classroom. 790
